

# Enowars 6 post mortem

Underleaf

---

Lenard Mollenkopf

- Echten Service nachbauen
- Service nachbauen den man danach noch verwenden könnte
- Overleaf als Vorbild

# Was ist Overleaf?

- Kollaborativer  $\text{\LaTeX}$ -Editor
- Workflow: Account erstellen  $\rightarrow$  Projekt erstellen  $\rightarrow$  Dokument schreiben  $\rightarrow$  Dokument kompilieren  $\rightarrow$  repeat
- Payed Features:
  - Synchronisation von Projekt und einem git-repo (nur in der cloud Version)
  - Kompilieren in isolierten Containern (nur in cloud und enterprise Version)

# Was ist Overleaf?

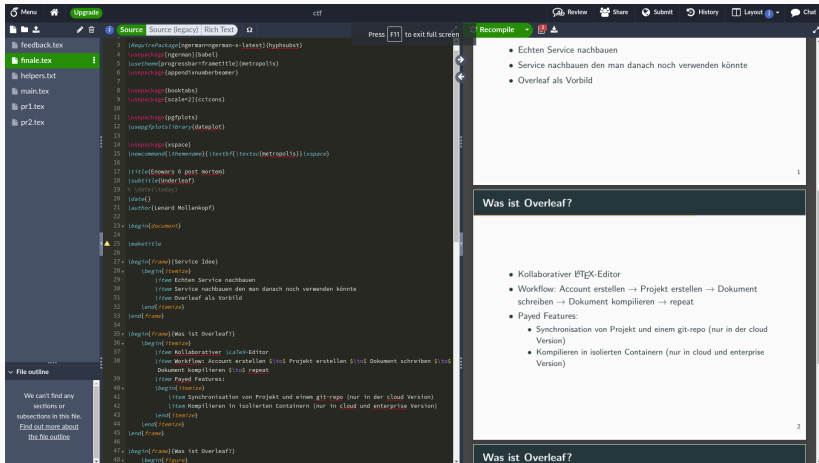

Abbildung 1: Screenshot von <https://overleaf.com>

# Die Kopie - underleaf

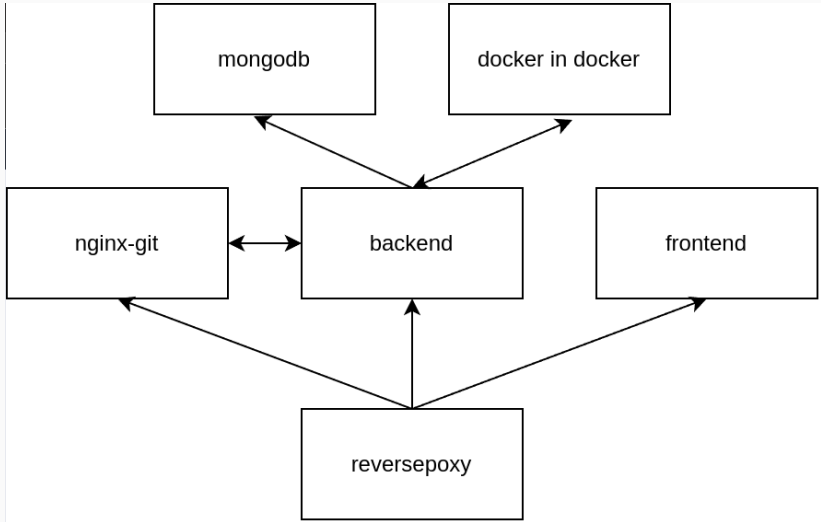

The screenshot displays the Underleaf web interface. On the left, a sidebar contains a file explorer with 'main.tex' and 'overleaf-sc.png', and buttons for 'Create new file', 'Compile / Save', 'Commit', 'Push', 'Pull', and 'Copy remote url'. The main area shows a LaTeX document with the following code:

```
15 \newcommand{\themename}{\texttt{\textsc{metropolis}}\hspace{1cm}}
16
17 \title{Ennors & post mortem}
18 \subtitle{underleaf}
19 % \date{\today}

On the right, a dark sidebar contains two sections titled 'Was ist Overleaf?'. The first section lists features: 'Echten Service nachbauen', 'Service nachbauen den man danach noch verwenden könnte', and 'Overleaf als Vorbild'. The second section lists features: 'Kollaborativer LaTeX-Editor', 'Workflow: Account erstellen  $\rightarrow$  Projekt erstellen  $\rightarrow$  Dokument schreiben  $\rightarrow$  Dokument kompilieren  $\rightarrow$  repeat', and 'Payed Features: Synchronisation von Projekt und einem git-repo (nur in der cloud Version), Kompilieren in isolierten Containern (nur in cloud und enterprise Version)'. Below the second section is a screenshot of the Overleaf interface, labeled 'Abbildung 1: Screenshot von https://overleaf.com'.

<sup>3</sup><https://github.com/substack/git-http-backend>

- Git kann symlinks
- `express res.download(path)` folgt symlinks
- kaputte Prüfung, ob Pfad erlaubt ist

# Erste Schwachstelle (Code)

```
8
9 export const downloadFile: RequestHandler = async function (req, res, next) {
10   try {
11     const projPath = resolve(getProjectPath(req.params.id));
12     const reqPath = req.params[0];
13     const path = resolve(projPath, reqPath);
14
15     if (await symlinkPathResolvesTo(path, getProjectPath("")) ) {
16       if (!(await exists(path))) {
17         res.status(404).send("404 file not found");
18         return;
19       }
20
21       if ((await fs.lstat(path)).isDirectory()) {
22         res.status(403).send({ status: "path is a directory" });
23         return;
24       }
25
26       if (path.startsWith(resolve(projPath, ".git"))) {
27         res.status(403).send({ status: "path is in .git" });
28         return;
29       }
30
31       res.download(path);
32     } else {
33       res.status(403).json({ status: "File not accessible" });
34     }
35   } catch (e) {
36     next(e);
37   }
38 }
```

Abbildung 4: Ausschnitt von downloadFile.ts

- $\text{\LaTeX}$  kann RCE, da `-shell-escape` an ist<sup>4</sup>
- Docker soll Schutz bieten
- Docker isoliert Netzwerk nicht stark genug
- db ist über IP und „db“ erreichbar

---

<sup>4</sup><https://0day.work/hacking-with-latex/>

## Zweite Schwachstelle (Exploit)

- $\text{\LaTeX}$  macht Verbindung zu db und Exploiter auf
- Exploiter liebt Daten aus der Datenbank aus
- Profit

- reverseproxy prüft Zugang zu /git per auth\_request an /api/auth/basic
- httpBasic.ts ließt Projekt Id aus „x-original-url“
- Aber FALSCH!

## Dritte Schwachstelle (Code)

```
7   try {
8       const url =
9         typeof req.headers["x-original-url"] === "string"
10        ? req.headers["x-original-url"]
11        : "in://valid";
12       const originalUrl = new URL(url);
13
14       if (
15         originalUrl.pathname.startsWith("/git/") &&
16         typeof originalUrl.pathname.split("/")[2] === "string"
17       ) {
18         const header = req.headers["authorization"];
19         if (header && header.startsWith("Basic ")) {
20           const base64 = header.split(" ")[1];
21           const [username, password] = Buffer.from(base64, "base64")
22             .toString()
23             .split(":");
24
25           if (await checkLogin(username, password)) {
26             if (
27               await canModifyProject(username, originalUrl.pathname.split("/")[2])
28             ) {
29               res.json(status_ok);
30               return;
31             }
32           }
33         }
34       }
35
36       res.status(401).json({ status: "unauthorized" });
```

Abbildung 5: Ausschnitt von httpBasic.ts

Demo

- *„A bit above mid”*
- *„Had some issues. Rendering didnt work at atl. ”TypeError: crypto.subtle is undefined”. Didn’t look at it any further.”*
- *„The dev instructions on the readme did not work. The bug that was being exploited took me two hours to triage properly after I had reproduced it from pcaps, so props for that.”*
- *„fun challenge. restriction to container was engaging”*
- *„interesting one! but when I tried to find a fix, our vm started crashing constantly.”*
- *„interesting unintended exploits (git path traversal) I don’t like config bugs (mongodb)”*
- *„I couldn’t render the documents”*

- I had fun with this challenge, probably in parts because we first-blooded it :D
- It felt overwhelming when first looking at it (so many containers, sub-folders, code). In hindsight I still feel like it could have been simpler and still include the same bugs. Having to read more code does not make a challenge more fun, it usually only adds pain.
- In our exploit we deleted more files that we needed to (out of laziness, `rm *` is short :P). We were told to stop it because it created a race condition between exploits. While I agree that it could remove the fun, I think should 100% be prevented by the service. Please implement the services in a way that does not allow stuff that you don't want to happen. Of course, no software is flawless and unintended bugs also happen in CTF challenges.

- I liked the symlink/download bug more than the DB default credentials bug. The second one required far more exploit engineering (find the DB IP, talk to mongo without a mongo client present) while it was a lame bug (default creds) that was easy to fix (change password or add network separation).
- The PoW was annoying for exploitation. I get why you had to put it there, but it first increased load on our exploit thrower and then distracted us because we had to come up with a more clever way of computing and reusing the PoW between exploits.
- Having Docker and docker-compose files is great to reproduce a local setup. Some things were a little counter-intuitive, e.g. having to restart the reverse proxy after changing the backend, and that changing the db password env var only influences the db password during first creating of the container.

# What worked?

- Mittlere Wertung im SLA
- Meisten Vulns gut angekommen
- Vuln und Fix nicht offensichtlich

# What did not work?

- `Crypto.subtle` nur über `https` oder `localhost`.
- Viel Code / Komplexität
- Probleme mit erstem Start / dev setup
- Unintended Vulns

- Service sollte *gutes* Logging haben
- Defense in Depth ist auch wichtig, wenn sich schon viele den Code angeguckt haben
- *Performance Matters* geht nicht im Nachhinein
